APPENDIX B VERSION WITH MARKINGS TO SHOW CHANGES MADE 37 C.F.R. § 1.121(b)(iii) AND (c)(ii)

CLAIMS:

- 1. (Amended) A MOS gated device which is resistant to single event radiation failure and having improved total dose radiation resistance; said device comprising:
 - a P-type substrate having substantially flat, parallel upper and lower surfaces;
- a plurality of laterally spaced N-type body regions extending from said upper surface into said substrate;
- at least one respective P-type source region formed in each of said body regions in said upper surface of said substrate and defining a respective channel region in said upper surface in said N-type body region;
- a gate electrode comprised of p-type polysilicon <u>including boron dopants</u> disposed atop and insulated from said channel region and operable to invert said channel region in response to the application of a suitable gate voltage to said gate electrode said gate being insulated from said channel region by a gate oxide layer comprising silicon dioxide, said gate oxide layer being radiation hardened and less than 1000Å thick; and
- a source electrode disposed atop said upper surface and connected to said at least one P-type source region.
